Sync Introduction

This guide has been written to assist those responsible for tape management with the process of integrating their backup software or tape management system with the TapeTrack Media Management Software.

For those who have their own TapeTrack Framework Server, these instructions relate to connecting to your own system, while, for those who use TapeTrack via a relationship with their data protection provider, these instructions relate to connecting into your vendor's system.

Prerequisite knowledge

Knowledge of the following skills would be advantageous in implementing TapeTrack synchronization:

- Experience with a text file editor such as Windows Notepad or vi.
- Experience with a task schedule such as Windows Task Scheduler or crond.
- Experience with the backup software you are synchronizing.
- Experience with Windows DOS batch scripting, or UNIX shell scripting.

What's in this document

This document will:

- Describe what synchronization is from a TapeTrack perspective,
- Outline the benefits of synchronizing TapeTrack with your backup software,
- Outline the prerequisites and components required for synchronization,
- Provide a reference for the synchronization definition language, and,
- Provide examples of integration with various backup software solutions.

Quick-start

The goal of this document is to be comprehensive reference. In the event that the reader is under time constraints, the following sections should be sufficient to implement synchronization:

- Downloading and Installing the software
- Synchronization prerequisites
- Implement synchronization based upon the example that matches your backup solution.
    - Backup Exec
    - Commvault
    - Data Protector
    - NetBackup
    - NetWorker
    - Tivoli Storage Manager
    - VEEAM

What is synchronization?

TapeTrack's Synchronization Suite is a powerful toolkit that allows you to set fields within TapeTrack based upon the values of fields within your backup or tape management software.

How does synchronization work?

The logic flow of synchronization is as follows:

- Load the definition file to instruct the program on where to get the data and how to interpret the data.
- Logon to the TapeTrack Framework Server
- Read each record from the data source, establish each of the fields to be synchronized for each record.
- On the first record, or on any record where the Customer and/or Media scope change, download a cache of Volume information from the TapeTrack Framework Server.
- Where the Volume information has changed apply the update to the TapeTrack Server.
- On the last record from the data source print statistics about the update session.

To reduce the overhead of retrieving records, when the Customer and/or Media scope change all information on all Volumes within the current scope is downloaded and loaded into a cache.

Where the Customer and/or Media scope do not change this means that the synchronization program only needs to download this information once.

Care should be taken not to randomize Volumes within a Customer and or Media scope as this will degrade the performance of the program.

If Volume scope is randomized it is strongly recommended that the data source be sorted as a step prior to synchronization.
